Abstract—The purpose of this study was to determine the effect of a 10-week training program on the heart rate (HR) and heart rate reserve (HRR) of sedentary middle-aged men. The subjects were 15 men, 40 to 50 years old, who were sedentary and had no cardiovascular disease. They were randomly assigned to a 10-week training program or a control group. The training program consisted of 30 minutes of aerobic exercise, 3 times a week, at 60% of the maximum HR. The control group did not exercise. The HR and HRR were measured at rest and during exercise at the beginning and at the end of the 10-week period. The results showed that the training program had a significant effect on the HR and HRR of the subjects. The HR and HRR were significantly lower at rest and during exercise at the end of the 10-week period compared to the beginning of the period. The control group did not show any significant changes in HR and HRR. The results suggest that a 10-week training program can improve the cardiovascular fitness of sedentary middle-aged men.

17. **Answer: C** The patient is a 40-year-old male with a 10-year history of type 2 diabetes mellitus. He has been taking insulin for the past 5 years. He has been experiencing frequent hypoglycemic episodes, which are relieved by eating. He has also been experiencing weight loss and fatigue. The most likely cause of these symptoms is insulin resistance, which is a common complication of type 2 diabetes mellitus. Insulin resistance occurs when the body's cells do not respond properly to insulin, leading to high blood sugar levels. This can cause the body to produce more insulin, which can lead to hypoglycemia. Weight loss and fatigue are also common symptoms of insulin resistance.
