Graph Clustering David A. Bader, Henning Meyerhenke, Peter Sanders, Dorothea Wagner, 2013-03-18 Graph partitioning and graph clustering are ubiquitous subtasks in many applications where graphs play an important role. Generally speaking, both techniques aim at the identification of vertex subsets with many internal and few external edges. To name only a few problems addressed by graph partitioning and graph clustering algorithms are: What are the communities within an online social network? How do I speed up a numerical simulation by mapping it efficiently onto a parallel computer? How must components be organized on a computer chip such that they can communicate efficiently with each other? What are the segments of a digital image? Which functions are certain genes most likely responsible for? The 10th DIMACS Implementation Challenge Workshop was devoted to determining realistic performance of algorithms where worst case analysis is overly pessimistic and probabilistic models are too unrealistic. Articles in the volume describe and analyze various experimental data with the goal of getting insight into realistic algorithm performance in situations where analysis fails.

Analysis and Enumeration Andrea Marino, 2015-03-23 In this work we plan to revise the main techniques for enumeration algorithms and to show four examples of enumeration algorithms that can be applied to efficiently deal with some biological problems modelled by using biological networks: enumerating central and peripheral nodes of a network, enumerating stories, enumerating paths or cycles, and enumerating bubbles. Notice that the corresponding computational problems we define are of more general interest and our results hold in the case of arbitrary graphs. Enumerating all the most and less central vertices in a network according to their eccentricity is an example of an enumeration problem whose solutions are polynomial and can be listed in polynomial time, very often in linear or almost linear time in practice. Enumerating stories, i.e. all maximal directed acyclic subgraphs of a graph G whose sources and targets belong to a predefined subset of the vertices, is on the other hand an example of an enumeration problem with an exponential number of solutions that can be solved by using a non trivial brute force approach. Given a metabolic network, each individual story should explain how some interesting metabolites are derived from some others through a chain of reactions by keeping all alternative pathways between sources and targets. Enumerating cycles or paths in an undirected graph such as a protein-protein interaction undirected network is an example of an enumeration problem in which all the solutions can be listed through an optimal algorithm, i.e. the time required to list all the solutions is dominated by the time to read the graph plus the time required to print all of them. By extending this result to directed graphs, it would be possible to deal more efficiently with feedback loops and signed paths analysis in signed or interaction directed graphs such as gene regulatory networks. Finally, enumerating mouths or bubbles with a source s in a directed graph that is enumerating all the two vertex disjoint directed paths between the source s and all the possible targets is an example of an enumeration problem in which all the solutions can be listed through a linear delay algorithm, meaning that the delay between any two consecutive solutions is linear. By turning the problem into a constrained cycle enumeration problem, such patterns in a de Bruijn graph representation of the reads obtained by sequencing are
