ABSTRACT

While face, object, and scene recognition are often studied at a basic categorization level (e.g. “a face”, “a car”, “a kitchen”), we frequently recognize individual items of these categories as unique entities (e.g. “my mother”, “my car”, “my kitchen”). This recognition of individual identity is essential to appropriate behaviour in our world. However, relatively little is known about how we recognize individually familiar visual stimuli. Using event-related brain potentials, the present study examined whether and to what extent the underlying neural representations of personally familiar items are similar or different across different categories. In three experiments, we examined the recognition of personally highly familiar faces, animals, indoor scenes, and objects. We observed relatively distinct familiarity effects in an early time window (200–400 ms), with a clearly right-hemisphere occipito-temporal scalp distribution for human faces and more bilateral and posterior distributions for other stimulus categories, presumably reflecting access to at least partly discrete visual long-term representations. In contrast, we found clearly overlapping familiarity effects in a later time window starting 400 to 500 ms after stimulus onset, again with a mainly right occipito-temporal scalp distribution, for all stimulus categories. These later effects appear to reflect the sustained activation of conceptual properties relevant to any potential interaction. We conclude that familiarity for items from the various visual stimulus categories tested here is represented differently at the perceptual level, while relatively overlapping conceptual mechanisms allow for the preparation of impending potential interaction with the environment.

1. Introduction

Imagine getting up in the morning and walking into the kitchen. Typically, the situation in front of you will be very familiar. You recognize the arrangement of the room and the furniture within it: as your kitchen, the person sitting at the table as your partner, the fairy thing jumping up as your leg as your dog, and the coffee cup on the table as an old one from your student days but not your favourite. We constantly recognize individual people, as well as unique scenes, objects, and animals, and this has huge behavioural consequences. For instance, it would very likely influence your next actions if the animal in your kitchen was not your, but a completely unfamiliar dog. Accordingly, it is crucial that we recognize the visual stimuli around us not only as exemplars of visual categories (a face, a dog, a coffee cup), but as unique, individual entities. Here, we investigated the neural processes underlying the identification of visual stimuli that are individually familiar to

Psychological research has investigated face, scene, and object recognition for decades (e.g., Saksida, 1972; Bruce & Young, 1986; Marr & Neisser, 1978). However, relatively little is known about the representation of unique identity, and how similar the representations for different stimulus categories are. In all cases, the recognition of a unique entity requires the matching of a visually perceived stimulus with a long-term memory representation. Importantly, as we recognize known faces, objects, and scenes across a wide range of viewing conditions (e.g. with changing lighting, viewing angles etc.), such representations need to allow for identification from a wide range of highly variable images. Understanding how visual perceptual mechanisms cope with image variability has important theoretical implications. For instance, it is now well-established that familiar faces are processed fundamentally differently from unfamiliar faces (Young & Burton, 2017, 2018). The same face can look very different in different circumstances,
