LABRADORITE

The calcium-rich, middle-range member of the plagioclase feldspars, labradorite is characterized by its schiller effect—a rich play of iridescent colors, mainly blue, on cleavage surfaces. Specimens are generally blue or dark gray but can also be colorless or white. When transparent, labradorite is yellow, red, orange, or green. This mineral seldom forms crystals, but when crystals do occur, they are tabular. It most often forms masses with crystals that can be microscopic or up to 3 ft (1 m) or more wide.

Labradorite is a major constituent of certain medium-silica and silica-poor igneous and metamorphic rocks, including diorite (p.264), gabbro (p.265), basalt (p.273), andesite (p.275), and amphibolite (p.296). Gem-quality labradorite from Finland is known as spectrolite.

**Semiprecious gemstone**

The polished oval of labradorite in this choker beautifully displays the stone's rainbow iridescence.
