A review of existing approaches and methods to assess climate change vulnerability of forests and forest-dependent people Food and Agriculture Organization of the United Nations, 2018-11-29

Until recently considerably more attention was paid to using forests to mitigate climate change through the absorption of carbon dioxide CO₂ from the atmosphere than there was on considering the need to adapt forests to avoid the worst effects that climate change could have on them The switch from a mitigation heavy approach to one that considers adaptation in a more balanced manner underscores the need to have approaches to assess the vulnerability of forests to climate change One reason for this more balanced focus may be due to the realization by the broader public governmental organizations and the forest science community that the climate change that has already occurred is permanent in human terms because it takes centuries for much of the CO₂ emitted from fossil fuel sources to be removed from the atmosphere There are already substantial impacts that are being seen in the world's forests These impacts are certain to continue increasing until CO₂ emissions drop to lower levels For that reason adaptation of the world's forests requires attention The approaches to assessing vulnerability can be categorized according to the focus they each provide Contextual vulnerability addresses current issues of climate and is usually evaluated using participatory techniques with people who live in or work with forests Outcome vulnerability looks at the biophysical vulnerability of forests it is often used to assess the cause and effect of climate change on a biological system Vulnerability assessments can be highly technical and quantitative using advanced computer programs and geographic information systems or they can be based on social science approaches to obtaining qualitative information from people
