

BREEDING BUNNIES

Safety: There are no special safety considerations for this activity.

Introduction

In this activity, you will examine evolution via natural selection in a small population of wild rabbits. **Evolution** is a change in the frequency of alleles in a population over a period of time. Breeders of rabbits have long been familiar with a variety of genetic traits that affect the survivability of rabbits in the wild, as well as in breeding populations. One such trait is the trait for furless rabbits (naked bunnies). This trait was first discovered in England by W.E. Castle in 1933. The furless rabbit is rarely found in the wild because the cold English winters are a definite selective force against it.

Natural selection is the process of unequal reproductive success or "reproduction of the fittest". How does natural selection affect allele frequency over several generations? You'll address this question by creating a hypothesis and testing it with a population of bunnies.

In your population of bunnies, there are two **alleles** - F, the allele for fur, and f, the allele for nakedness. F is **dominant**, and f is **recessive**. The dark beans represent the F allele for fur, and the white beans represent the f allele for nakedness. The table below describes the possible **genotypes** and **phenotypes** from these two alleles. Remember, each rabbit gets two alleles for the fur trait.

Genotypes	Phenotypes
FF (2 dark beans)	fur
Ff (1 dark bean, 1 white bean)	fur
ff (2 white beans)	naked

(Note – if you are unfamiliar with any of the terms above in bold, be sure to look these up in your textbook before completing the lab.)

Equipment

Dark and white beans
1 large container
3 smaller containers

Generate your hypothesis

1. What do you think will happen to the frequency of F alleles and f alleles in the population of rabbits after 5 generations, where naked bunnies (ff) are selected against (do not survive)? State your hypothesis below:
